Escogí utilizar instancias de tipo m5.xlarge para hacer las pruebas en EMR ya que los clústers pedían instancias grandes para poder llevar a cabo las operaciones con Hadoop. Utilicé 2 5 y 7 núcleos ya que eran números equilibrados, además, a partir de 8 núcleos el clúster se volvía más inestable y empezaba a fallar.

En los datos de Hadoop no están los datos de S3 ya que evidentemente en local no se interactúa con S3. En el caso de Hadoop hay un único nodo pseudodistribuido, mientras que en EMR el número más bajo es de 2. Se puede observar como a medida que el número de núcleos aumenta, las estadísticas relacionadas con bytes y los tiempos se mantienen iguales o aumentan, nunca disminuyen. Hay otras estadísticas directamente relacionadas con el número de nodos, como el *Launched reduce tasks* que puede obtenerse como el número de nodos multiplicado por 2 y menos 1. En general las estadísticas presentan una tendencia común.
